13. ABSTRACT				

This report summarizes investigations done during the contract period of January 1, 1975, to June 30, 1975. It describes work dealing with improvements of advanced measurement techniques. Chapter 1 deals with the computer generation of Kikuchi patterns needed for complex structural analysis of crystal defects in silicon. The program is applicable to a large variety of problems and can be used to generate Kikuchi maps for different crystal structures, each desired crystal orientation, and electron energy. The program can also be used to generate channeling patterns for scanning electron microscopy application. The report provides a complete set of computer-generated Kikuchi maps for silicon and 200 keV electrons. A complete program in Fortran IV using an IBM 1800 computer is also given. The second part describes the application of MOS C-V and MOS G-V measurements for the evaluation of epitaxial films on silicon or inculator substrates. It is shown that the presence of an underlying junction requires important precautions with use of the MOS C-V measurement technique. The junction requires an increased number of components in the equivalent network, which impedes the analysis. This chapter shows how to solve the problem. Values for MOS dot diameter, layer and substrate resistivity, oxide thickness, etc. are given and refer to ranges where meaningful lifetime measurements can be carried out.

#### LIST OF INVESTIGATORS

The project is supervised by Dr. G. H. Schwuttke, principal investigator. The following people contributed to the work in this report:

Dr.	W.	Fahrner	-	Investigator (Visiting Scientist)
Dr.	н.	Kappert	-	Investigator (Visiting Scientist)
Dr.	G.	H. Schwuttke	-	Principal Investigator
Mr.	E.	F. Gorey	-	Technical Support
Mr.	c.	P. Schneider	-	Technical Support
Mr.	н.	Ilker	-	Technical Support

#### SUMMARY

This report summarizes work done during the contract period of January 1, 1975 to June 30, 1975. It describes research programs dealing with improvements of advanced measurement techniques. Such improvements became imperative during the course of the contract work and are needed for subsequent structural and electrical characterization of impact sound stressed (ISS'ed) silicon wafers before and after oxidation and epitaxy.

The first chapter advances the analytical capabilities of transmission electron microscopy through the application of computer-generated Kikuchi patterns. Kikuchi lines in electron diffraction patterns are used for complex crystal defect analysis based on two-beam orientation of the specimen. Since our Hitachi microscope permits seeing only about 4° of a diffraction pattern it is impossible to index Kikuchi lines without a detailed Kikuchi map. Therefore it was necessary to computer-generate Kikuchi plots. A program for the generation of such plots was written. The program was used to generate Kikuchi maps for the three main orientations (001), (011) and (111) for Si and 200 keV electrons.

An additional benefit of this computer program is that it is applicable to a large variety of problems. By changing proper parameters the same program can be used to generate maps for all kinds of crystal structures, each desired crystal orientation, electron energy, crystallographic order and maximum index-number of lines. The program considers also parameters such as map-scales and camera length of the microscope.

In addition the program can be used to compute and print out channeling patterns used for crystal orientation analysis in the scanning electron microscope. The report provides a complete set of Kikuchi maps for silicon and 200 keV electrons as well as the complete program to generate other patterns.

The second part of the report describes the application of MOS C-V measurements to the evaluation of epitaxial silicon films on silicon or insulator substrates. It is shown that the presence of a semiconductor junction under the MOS structure requires certain considerations to be made if meaningful measurements are to be obtained. The junction requires an increased number of components in the equivalent network, which impedes the analysis.

A solution to this problem is given. If one side of the junction is oxidized, a quasi MOS structure is obtained. The equivalent network of such a structure is discussed and the conditions for MOS C-V and G-V measurements are given. When the MOS admittance can be measured the following information can be obtained:

- Surface-state density, the corresponding capture cross sections, the charge density in the oxide, and deep energy levels.
- 2. The doping concentration.
- 3. The minority carrier lifetime.

The discussion concentrates on the measurement of minority carrier lifetime in epitaxial silicon films. Values for layer and substrate resistivity, dot diameter, oxide thickness, etc., are given to establish the range for this "Quasi MOS Capacicance Technique."

Chapter 1

COMPUTER GENERATION OF KIKUCHI MAPS FOR TRANSMISSION ELECTRON MICROSCOPY (TEM) AND SCANNING ELECTRON MICROSCOPY (SEM) INVESTIGATIONS

by

H. Kappert

INTRODUCTION

Electron diffraction patterns of samples of very good crystalline perfection and of a thickness such that inelastic scattering of electrons is fairly high, show a distinct line structure superimposed on the background intensity. This line pattern is known as the Kikuchi pattern. A similar pattern (known as Coates or channeling pattern) appears in the SEM when the intensity of the backscattered electrons is recorded as an angular dependence of the incoming beam in reference to the sample orientation.

Several applications of the TEM technique such as Burgers vector determination, crystal orientation determination, and indexing of unknown spot pattern make use of such Kikuchi patterns (1-8). For such applications it is convenient to have Kikuchi maps which show the geometrical configuration of the pattern and give the indices of all lines in it.

One way to obtain such maps is to take many images in the TEM of overlapping parts of the diffraction pattern for different tilt angles of the specimen and assemble these images in a composite map. Another way is to generate plots of indexed

Kikuchi maps through a computer. The advantage of the second way is that once a program is available it is very easy to select any desired crystalline structure, sample orientation, different wavelength of electrons or even x-rays, scale of map, or order of Likuchi lines, just by changing some parameters in the program.

To generate Kikuchi maps very good instructions can be found in the literature (4,7,9). We followed mainly the recipe given by C. T. Young and J. L. Lytton (9).

#### GEOMETRY

Kikuchi lines are criginated by inelastically scattered electrons in the specimen. The energy losses of these electrons are small enough that they still can be considered coherent, but they have changed direction in reference to the primary electron beam. Therefore, in spite of the primary beam being off Bragg angle  $\theta$  for a certain set of net planes, a particular fraction of the inelastically scattered electrons makes a Bragg reflection at these planes, e.g., (h, k, l) in Fig. 1. This can be regarded as a virtual incoming electron beam for each set of net planes, which is split below the specimen into a transmitted and a diffracted part. We find this situation not only in the plane that corresponds to the plane of the drawing in Fig. 1 but in all directions whenever the Bragg

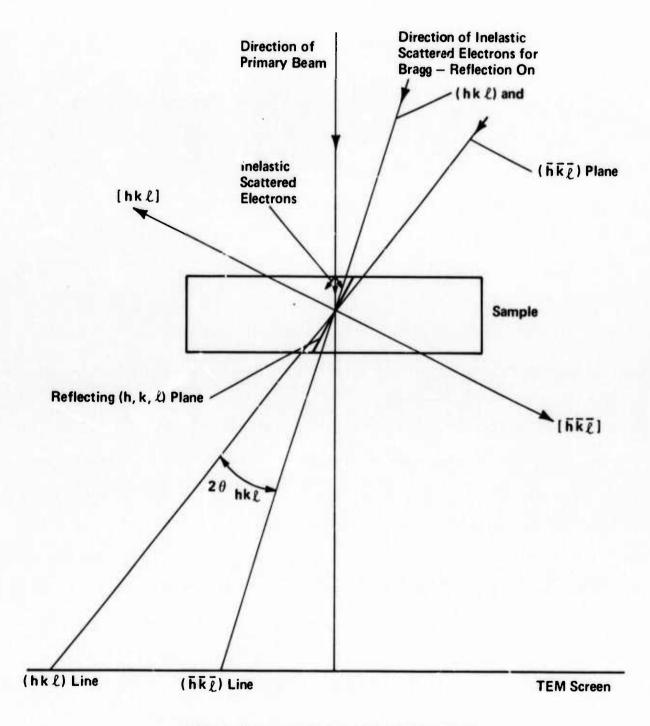

Fig. 1. Geometry for formation of Kikuchi lines.

condition is satisfied for the (h, k, 1) plane. Therefore all the directions of the particular fraction of elastically scattered electrons in Bragg conditions for a certain set of net planes (h, k, l) are represented by a cone (Fig. 2), where the cone axis is in the direction of the plane normal (h, k, l) and the half opening angle is 90°-0 (Kossel cone). The same geometry can be used for channeling pitterns in the SEM. In the SFM the primary beam itself has to be tilted along a cone surface to get a signal of the backscattered electrons with less an more intensity than for the background intensity that appears as dark or bright lines on the TV display.

The real Kikuchi line patte n is the intersection of all the cones produced by the different sets of net planes, with the image plane in the TEM below the specimen. The real channeling pattern is the intensity modulation of the backscattered electrons above the sample, as seen by the collector and displayed on the TV screen, dependent on the tilt angle of the primary beam in reference to the sample prientation.

The usual way to generate Kikuchi and channeling maps is to make a stereographic projection of all the cones, which are thus represented as circles on the projection sphere (Fig. 2). This may be done because the projection keeps the angles between intersecting lines or circles on the sphere constant, results in only small distortions of the distances especially

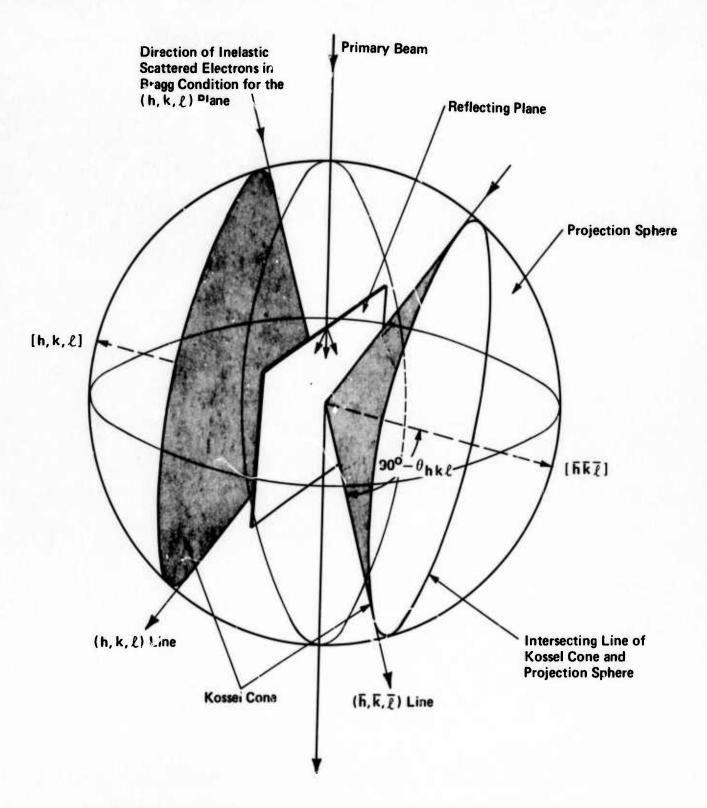

Fig. 2. Geometry of Kossel cones and their intersection with the projection sphere.

close to the center pole, and has the advantage that standard stereographic pole maps can be used for indexing purposes. The stereographic projection of the intersecting lines of the diffraction cones with the projection sphere appears as circles in the projection plane, which are called Kikuchi circles. The radius and center of each Kikuchi circle has to be calculated. Subsequently the part of the circle that is within the plotting area has to be determined and to be drawn.

#### ORIENTATION

Standard stereographic projections are made from G to O and are observed from the top, as shown in Fig. 3. The channeling patterns in the SEM are observed in the same way. To find the correct orientation between standard stereographic pole maps, channeling map and channeling pattern on the screen, we have only to consider which lenses are used to focus the primary beam onto the sample surface and how the tilt angle is related to the TV display.

The G to O direction of the standard stereographic projection, as shown in Fig. 3, is just the opposite to the direction in which the electrons go in the TEM to form the Kikuchi pattern on the screen. One gets around this orientation problem

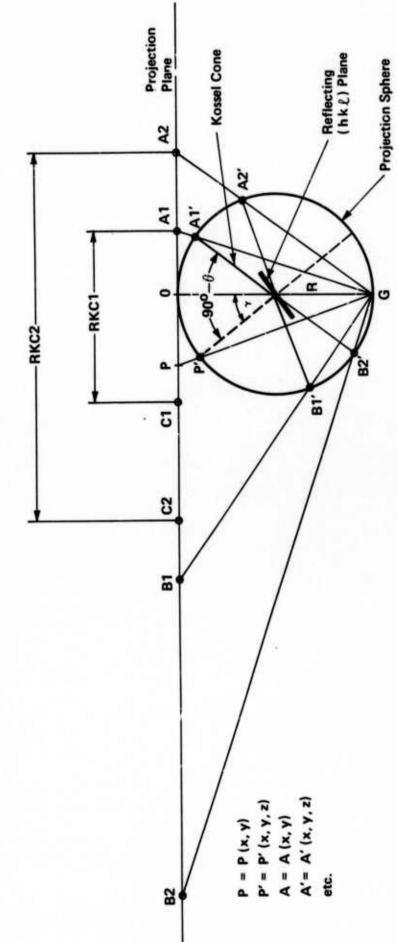

Fig. 3. Used projection and geometry to calculate radius and center of the Kikuchi circles.

by turning the projection upside down (1). Therefore standard stereographic projections have to be inverted for indexing purposes. Another possibility is to use the standard stereographic projection without inversion. This requires an adjustment of the Kikuchi maps such that the indexed reflections in the diffraction pattern correspond to the planes in the crystal. From the geometry shown in Fig. 2, one can see that the cone representing the directions of diffracted electrons intersects the projection sphere at the lower hemisphere as well as at the upper hemisphere. A downward projection—that is, the unconventional projection from 0 to G (Fig. 3)—would result in the real Kikuchi map as seen on the TEM screen.

An upward projection—that is, the conventional stereographic projection from G to O (Fig. 3)—results in the same map, except that this one is rotated by 180° in reference to the real Kikuchi pattern on the TEM screen. To do it this way was recently proposed by Head et al. (10). We decided to use this method because a rotation of 180° is more convenient than a mirror inversion, and we can use standard stereographic projections as in x-ray studies.

The correct orientation between the sample, the TEM micrograph, the diffraction pattern, standard pole map and Kikuchi map is found as follows:

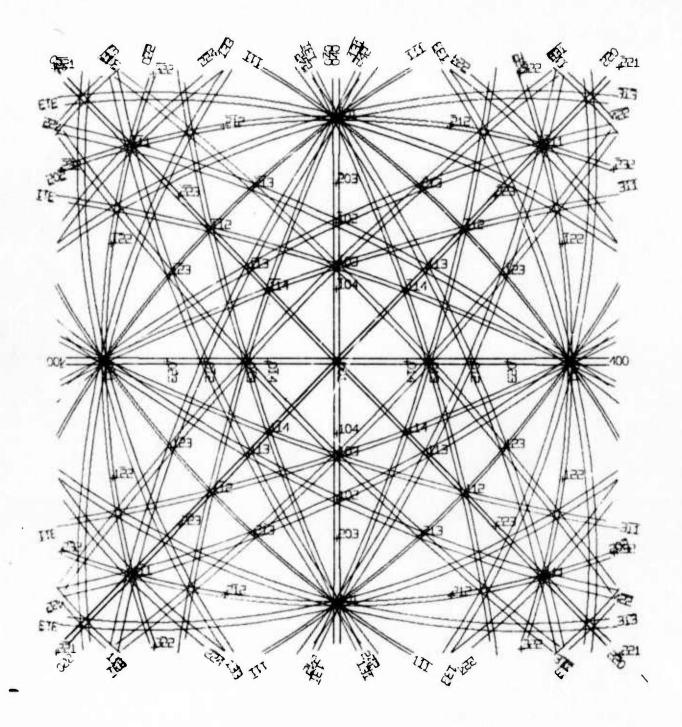

Fig. 4. (001) map for Si 200 keV, xo = yo = 11cm, R = 11cm, RMN = 2, SMSQ = 5.

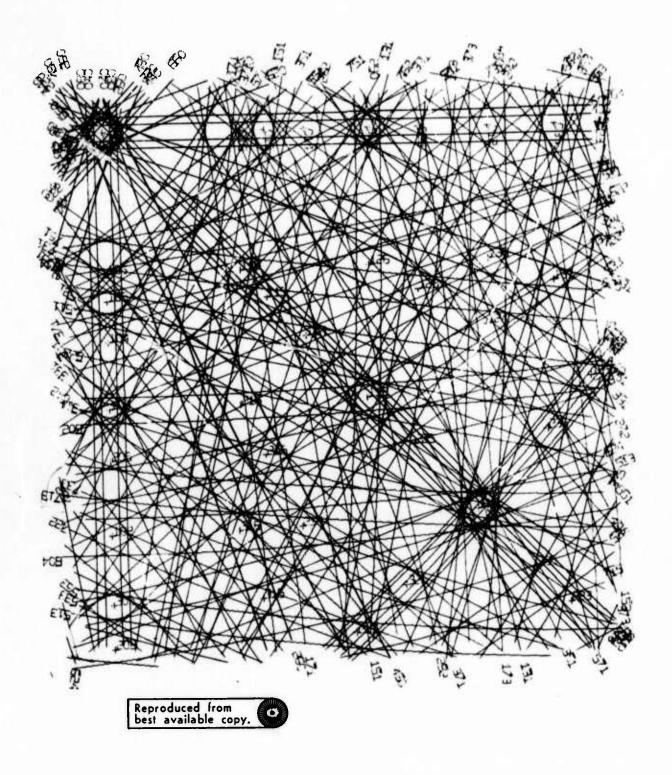

Fig. 5. (001) map for Si 200 keV, xc = yo = 20cm, R = 32cm, RMN = 4, SMSQ = 9.

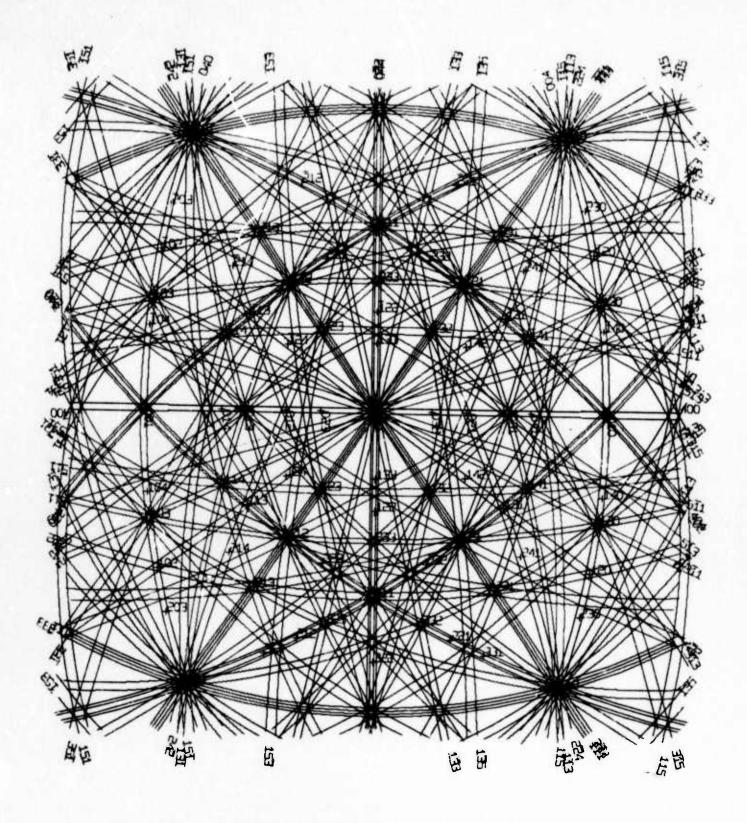

Fig. 6. (011) map for Si 200 keV, xo = yo = 12cm, R = 11cm, RMN = 4, SMSQ = 5.

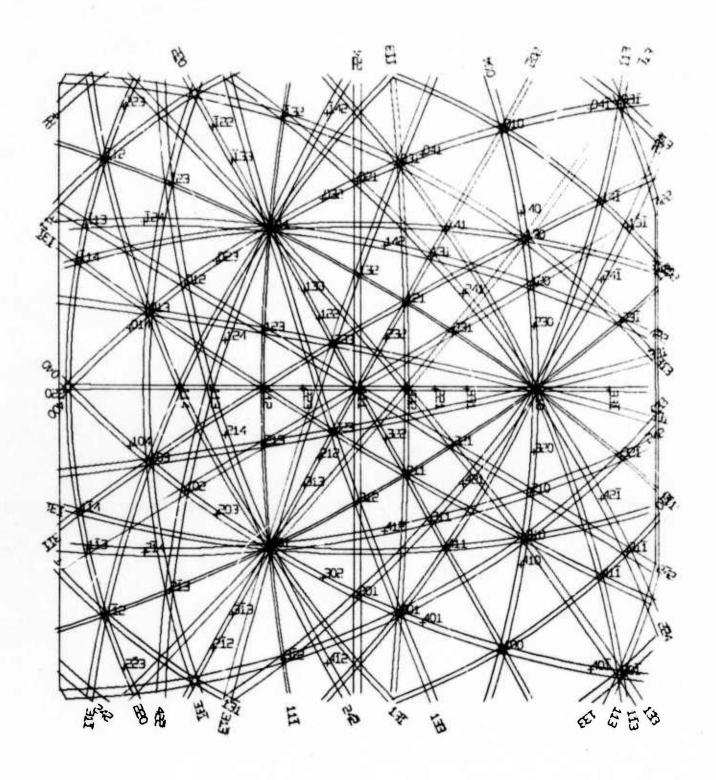

Fig. 7. (111) map for Si 200 keV, xo = yo = 12cm, R = 11cm, RMN = 2, SMSQ = 5.

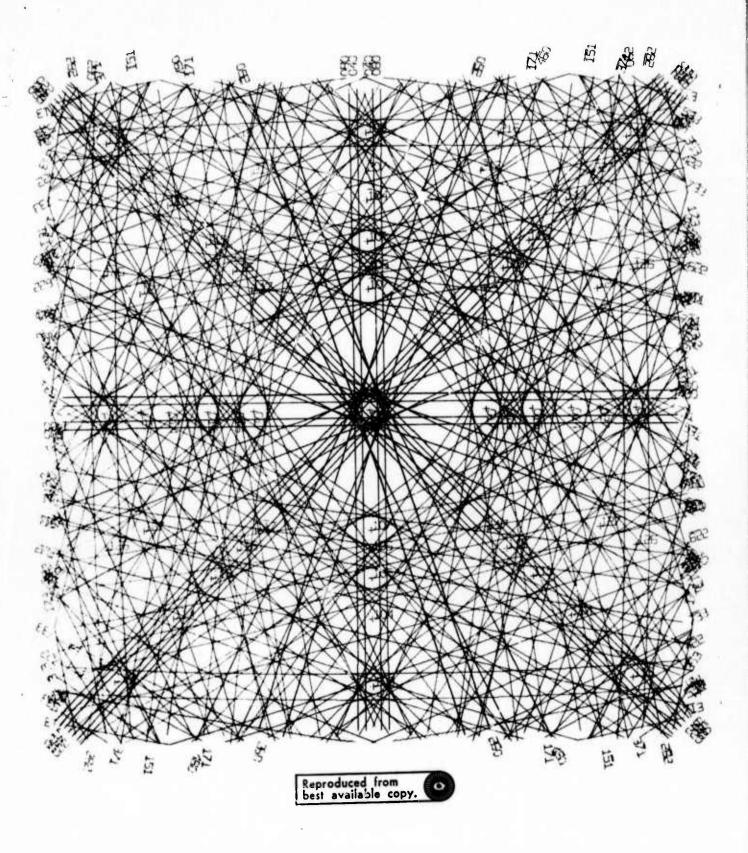

Fig. 8. (001) map for Si 200 keV, xo = yo = 12cm, R = 32cm, RMN = 4, SMSQ = 9.

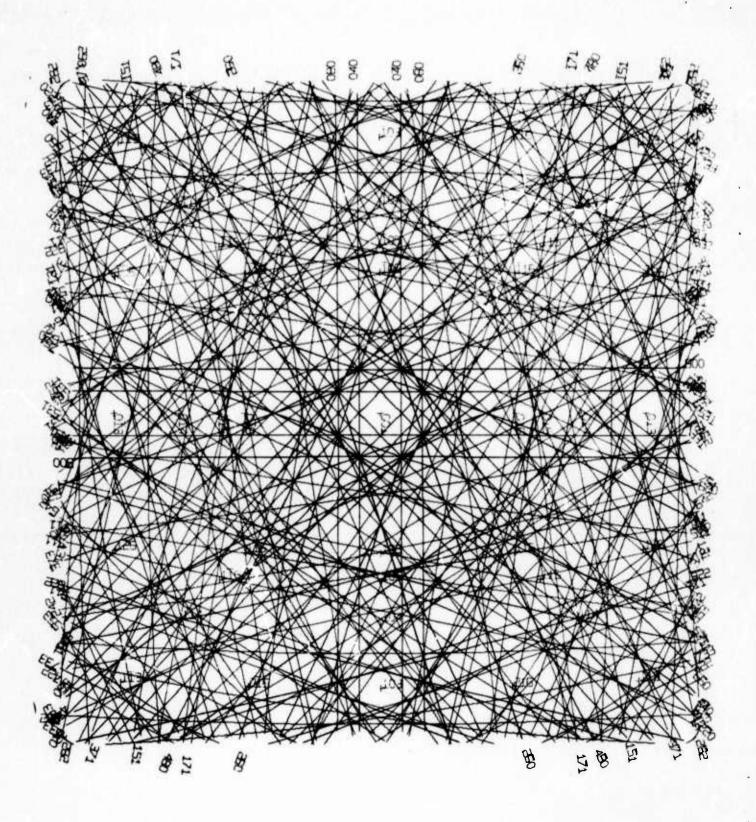

Fig. 9. (001) map for Si 30 keV, xo = yo = 12cm, R = 32cm, RMN = 4, SMSQ = 9.

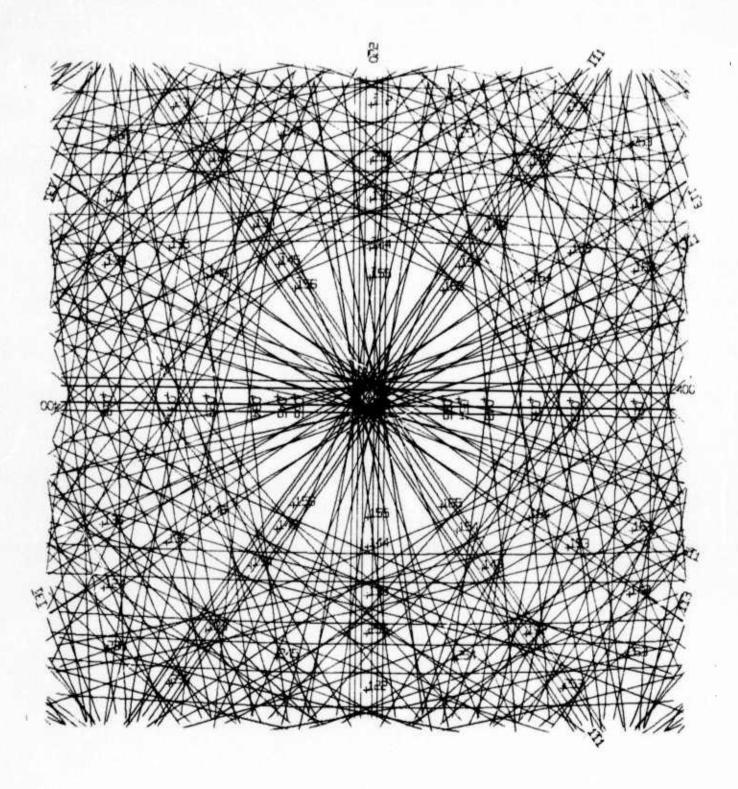

Fig. 10. (011) map for Si 200 keV, xo = yo = 12cm, R = 32cm, RMN = 4, SMSQ = 9.

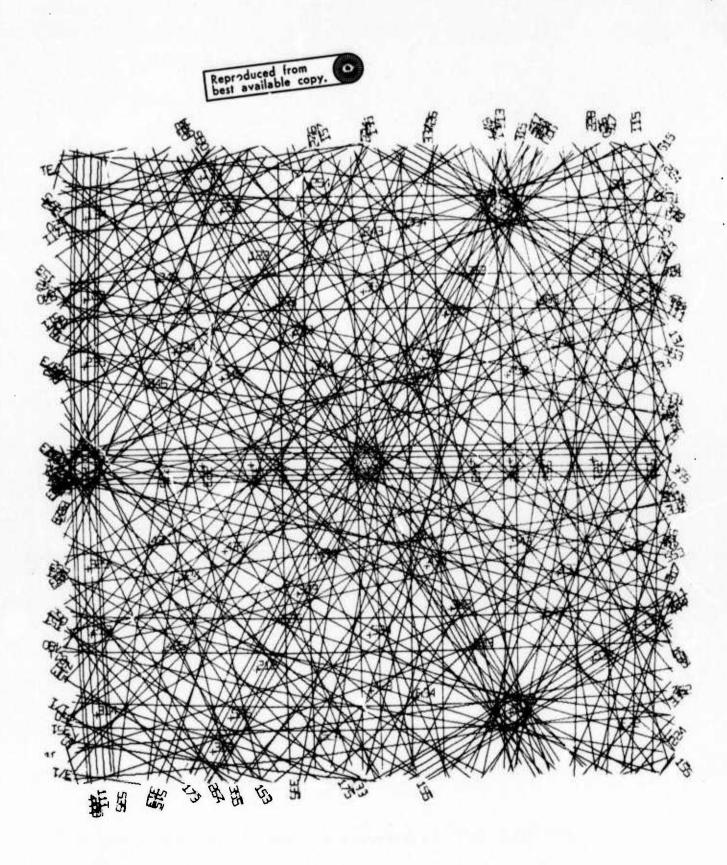

Fig. 11. (111) map for Si 200 keV, xo = yo = 12cm, R = 32cm, RMN = 4, SMSQ = 9.

- Consider the rotation between micrograph and 1. diffraction pattern that depends on the number of lenses used and their excitation.
- Orient the Kikuchi plot the same way as the TEM Kikuchi pattern and take negative values of the pole indices as plotted in the map.
- 3. Rotate a standard stereographic pole map with the same center pole as the Kikuchi plot by 180° in reference to the pole map plotted within the Kikuchi map.

To avoid any other inversion or rotation we have to use both negatives and prints of the micrograph as recorded in the TEM on the screen.

#### THE PROGRAM

The program is written in Fortran IV for an IBM 1800 computer. The time used to generate one plot depends on the number of lines that have to be plotted. For example, the plot shown in Fig. 4 takes less time than the plot shown in Fig. 6, where higher order and higher index lines appear. The time for the plot in Fig. 6 was about 50 min. The attached program was used for this plot. Figures 6-11 show different plots generated with the same program when parameters used are as described in each figure caption.

Steps of the program:

## 1. Selection of diffraction planes

The usual structure factor equation:

$$F = \sum_{j=1}^{n} f_{j} \exp \left[ 2\gamma i \left( u_{j} h + v_{j} k + w_{j} 1 \right) \right]$$
 (1)

is used to calculate the structure factors for silicon so that the planes can be selected which give the Bragg reflections. For this calculation the coordinates u, v, w of the position of the 8 atoms in the Si unit cell have to be put into (1). The Bragg equation is used in the form

$$\theta_{hkl} = \frac{\lambda}{2a} \sqrt{h^2 + k^2 + 1^2} = 0.0023 \sqrt{h^2 + k^2 + 1^2}$$
 (2)

for 200 keV electrons and Si samples to calculate the Bragg angles  $\theta_{\mbox{\footnotesize{khl}}}$  for each plane.

## 2. Transition to desired orientation with coordinates X31, X32, X33

The coordinate transformation

$$\begin{pmatrix} XH \\ XU \\ XL \end{pmatrix} = \begin{pmatrix} h_1/\sqrt{s_1} & k_1/\sqrt{s_1} & l_1/\sqrt{s_1} \\ h_2/\sqrt{s_2} & k_2/\sqrt{s_2} & l_2/\sqrt{s_2} \\ h_3/\sqrt{s_3} & k_3/\sqrt{s_3} & l_3/\sqrt{s_3} \end{pmatrix} \begin{pmatrix} XHS \\ XUS \\ XLS \end{pmatrix}$$
(3)

is used where  $(h_3, k_3, l_3) = (X31, X32, X33)$ . The other vectors  $(h_1, k_1, l_1)$  and  $(h_2, k_2, l_2)$  have to be chosen in accordance with a right-handed Cartesian system.  $s_i = h_i^2 + k_i^2 + l_i^2$ .

## Rejection of high-index and high-order planes

Planes of high-index numbers larger than a maximum number SMSQ =  $\sqrt{h^2 + k^2 + 1^2}$  have to be rejected; the same is true for planes of higher order than maximum order RMN.

## Calculation of coordinates in the projection plane

The coordinates of one intersection point of the diffraction cone with the projection sphere have to be calculated. For this purpose spherical polar coordinates are introduced. the calculation of the coordinates within the projection plane has to be performed by the equation

$$P_{x} = 2R \quad \tan \gamma/2 \frac{P_{x}'}{(P_{x}'^{2} + P_{y}'^{2})^{1/2}}$$

$$P_{y} = 2R \quad \tan \gamma/2 \frac{P_{y}'}{(P_{y}'^{2} + P_{y}'^{2})^{1/2}}$$
(4)

where  $\gamma = \cos^{-1} (P_z'/R)$ , as can be seen from Fig. 3.

## Determination of the radius and center of the Kikuchi circle

From Fig. 3 it can be deduced that the radius of the Kikuchi circle is

$$\overline{CA} = 1/2 (\overline{BO} + \overline{OA})$$
 (5)

and the coordinates of the circle center C are

$$CX = P_{x} (\overline{CO}/\overline{PO})$$

$$CY = P_y (\overline{CO}/\overline{PO})$$

### 6. Provision for an (x,y) array for the plot

Only a small part of the Kikuchi circle in an area with radius RI=SQRT (X0 x X0 + Y0 x Y0) around the center pole has to be plotted. Therefore it has to be checked whether a particular Kikuchi circle has a part of it inside this area. Then the circle equation

$$[X - CX]^2 + [Y - CY]^2 = R^2 = [\overline{CA}]^2$$
 (6)

is used to provide an array of 50 (x,y) pairs for the plotter.

## 7. Plotting section

A final check is made to find out which values of the array are inside the plotting square given by XO and YO. The

slope of the lines near the border of this square is determined in order to plot the indices of this Kikuchi line pair at the end of the line with the same slope.

### Plotting the pole map

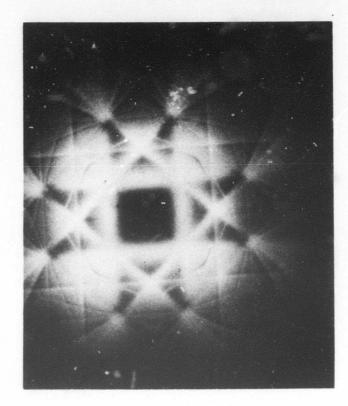

An extra program was written to produce pole maps of the same scale as the Kikuchi map. The steps are essentially similar to steps 2, 3, and 4 above.

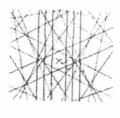

#### RESULTS

The size of each plot is about 24  $\times$  24  $cm^2$ , which is the maximum usable size of the plotter used. The numbers inside the map represent the indices of the pole where the location is indicated by a +. The numbers outside the map represent the indices of a certain Kikuchi line pair. The indices are plotted at one end of the respective Kikuchi line with the same slope as the lines at this end. Figures 4, 5, 6, and 7 represent (001), (011), and (111) Kikuchi maps with the same scale for Si with 200 keV electrons. Figures 8, 10, and 11 again represent (001), (011), and (111) Kikuchi maps for Si with 200 keV electrons but for about three times larger scale and with higher-order and higher-index lines. Figure 5 is a larger scale plot of the lower-right quadrant of Fig. 4; and Fig. 9 is the same plot as Fig. 8 but with 30 keV electrons and can be used as a map for channeling pattern for the SEM. Figure 12 gives several examples of Kikuchi poles as shown on the maps and in the TEM.

Chapter 2

ELECTRICAL CHARACTERIZATION OF QUASI MUS STRUCTURES ON SILICON by

W. R. Fahrner, E. F. Gorey, and C. P. Schneider

#### INTRODUCTION

Junctions are present in important devices, e.g., in buried-channel charge-coupled devices (CCDs) or in silicon on sapphire (SOS)-based integrated circuits. In order to optimize the performance of such a device--speed, transfer efficiency, etc.--the characterization of the electrical properties of the material is desirable. For homogeneous silicon, there are some standard techniques based on metal oxide semiconductor (MOS) capacitance measurements for this purpose. The presence of underlying junctions requires important precautions to be made with the use of MOS-CV measurement techniques.

Owing to the junction, the number of components of the equivalent network increases and the analysis is impeded. It will be shown in this paper how this problem can be solved. When one side of a junction described above is oxidized, a quasi MOS structure results. The equivalent network of such a structure is discussed in this paper, and the conditions for MOS C-V and G-V measurements are given. In the case where the MOS admittance can be measured, the following information can be obtained:

- 1. The surface-state density  $N_{ss}$  (1), the corresponding capture cross sections (2), the charge density in the oxide (3), and deep energy levels (4).
- 2. The doping concentration  $N_{D}$ .
- 3. The lifetime of the minority carriers (5).

Measurements on epitaxial junctions according to (3) have already been carried out (6) without an adequate the retical basis.

In this investigation, we are primarily interested in the measurement of lifetime, since this parameter is more sensitive to defects and impurities in the crystal than any other electrical parameter (7). Thus, in the section "Range of Quasi MOS Capacitance Technique," the values for layer and substrate resistivity, dot diameter, oxide thickness, etc., refer to ranges in which such lifetime measurements can be carried out.

## ANALYSIS OF EQUIVALENT NETWORK

In Fig. 1, a cross section of an oxidized n epitaxial layer on a p substrate is shown. The network of the structure consists of the oxide capacitance  $C_{ox}$ , the distributed layer resistance R of the n-layer, the distributed junction admittance  $Y_J = G_J + j\omega C_J$ , and the distributed substrate resistance  $R_s$ . A net consisting of buried layers each of 2.5 times 2.5 mm area with a spacing of 8 mm is diffused into the substrate prior to epitaxy. The doping profiles underneath A (off the

buried layer) and B (on the buried layer) are obtained by the spreading resistance technique (Fig. 2). The C-V curves for two dots off the buried layer are shown in Fig. 3. The dots have areas of 0.01765 and 0.00196 cm<sup>2</sup>. The same measurements are repeated for a <115> and a <100> oriented wafer with epitaxial layer resistivity of approximately 0.9 ohm-cm and of approximately 4- $\mu$ m epitaxial thickness. The substrate resistivity is 8 and 6 ohm-cm respectively (Fig. 4a,b). In these wafers, no buried layer is present.

The analysis of the data given in Fig. 3 reveals that the measured low-frequency capacitance in accumulation is identical with the oxide capacitance. This is confirmed through measurements on control wafers, by measuring the oxide thickness and the capacitances for different dot areas and comparing the ratios with the area ratios.

The dc voltage drop  $(v_J)$  across the junction is 0 since there is no dc current flow through the MOS structure.

The ac admittance is given by  $G_J$   $(v_J) + j\omega C_J$   $(v_J)$  with  $v_J = 0$ .  $G_J$  can be derived as  $G_J = dI_J/dv_J = I_o \times (q/kT) \times \exp(qv_J/kT)$ . In anticipation of the results, the lifetime of the epitaxial layer (which is heavily doped compared with the substrate and can be expected to give the major contribution to the dark current) is measured now to be approximately 1 µsec. With this

value and the given wafer data, one obtains I  $\sim$  10<sup>-9</sup> A, and thus  $G_J \sim 4 \times 10^{-8}$  exp  $(qv_J/kT)$  mhos. The capacitance  $\rm C_{J}$  is  $\sim$  20 nf at 0 Volt and  $\omega C_{J}^{} \sim 10^{-10}$  mhos for a frequency of 2 x  $10^{-3}$  Hz. (I and C have been calculated by means of Shockley's equation  $I_0 = qA \left(p_n \sqrt{D_p/\tau_p} + n_p \sqrt{D_n/\tau_n}\right)$  and the depletion approximation  $C_J = \varepsilon A \left(\frac{q}{2\varepsilon v_D} \cdot \frac{N_D \cdot N_A}{N_D + N_A}\right)^{1/2}$ .  $v_D$  is the diffusion potential. The other symbols have the usual meaning.) The ac admittance is resistance-controlled up to  $\sim$  1 Hz. Even in range f > 1 Hz, there is no influence of the junction admittance, since  $\omega C_{1} >> \omega C_{0x}$ . These considerations explain why a voltage-independent accumulation capacitance is measured over the usual frequency and bias range. The validity of the assumption on G  $(v_J)$ , C  $(v_J)$ , and the numeric values are found in good agreement with C  $(v_J)$  and differentiated I  $(v_J)$ curves measured after oxide removal and ultrasonic cutting (e.g.,  $C_{T}$  = 35 and 40 nf for dots cut at A and B, respectively).

The bulk resistance  $R_s$  of the substrate can be neglected as long as the resistivity is not too large. Experimentally, the upper limit was found to be approximately 50-100 ohm-cm and is theoretically given by the comparison of the  $RC_{ox}$  time constant with the measurement frequency of 1 MHz.

From the data given in Fig. 3 (i.e.:  $C_{ox} = 532 \text{ pf}$ ,  $C_{HF}$  (acc). = 415 pf), the lumped series resistance can be determined:

$$C_{HF} (acc) = C_{ox}/(1 + \omega^2 \tau^2)$$
 [1]

$$\tau = RC_{ox}$$
 [2]

This gives R=159 ohms. For the case of a buried layer underneath the dot, this value is reduced to R=88 ohms. (Note that in Fig. 2 the buried layer extends into the epitaxial layer due to outdiffusion.) When the dot area is reduced to  $0.00196~{\rm cm}^2$  and the capacitance to  $58~{\rm pf}$ , no dispersion is observed in accumulation up to 1 MHz. With the same values of R, one obtains now  $(\omega\tau)^2=(2\pi\cdot 10^6\cdot R\cdot C_{\rm ox})^2=3.4\times 10^{-3}$  and  $1\times 10^{-3}$ , respectively;  $C_{\rm ox}$  can be measured with 1 MHz.

Since the time constant of the surface states is usually observed in the kHz range, G(V) and  $G(\omega)$  measurements (2) are also feasible. (A G(V) and a  $G(\omega)$  curve is a plot of the total conductance G vs voltage or frequency at a fixed frequency or voltage respectively.) This is roughly checked by measuring G(V) in the kHz range. The typical peak due to surface states and its shift with frequency is observed.

From Fig. 4, one obtains R values of 220 ohms and 240 ohms for  $N_D = 5 \times 10^{15}$  and 4.8  $\times 10^{15}$  cm<sup>-3</sup>, respectively.

#### SPREADING RESISTANCE VS DOT DIAMETER

For frequencies  $\omega \leq 1/RC_{\rm ox}$ , the equipotential lines of the structure are schematically drawn in Fig. 5a. Therefore, one can assume a disk-like volume representing the epitaxial layer, in which the current flows (Fig. 5b). The voltage  $v_{\rm o}$  is applied at the inner area  $2\pi r_{\rm o} \cdot d_{\rm epi}$ ,  $d_{\rm epi}$  being the epitaxial layer thickness; the outer area at  $r_{\rm l}$  is grounded. A voltage dv drops across a volume increment 2 r  $\pi$  dr ·  $d_{\rm epi}$ :

$$dv = -i_{o} dR$$
(i<sub>o</sub> is the current caused by v<sub>o</sub>).
$$dR \text{ is defined by}$$

$$dR = \rho \cdot dr/A(r) = \rho \cdot dr/(2 \cdot \pi \cdot r \cdot d_{epi})$$

$$dv = -i_{o} \cdot \rho \cdot dr/(2 \cdot \pi \cdot r \cdot d_{epi})$$

$$v = -(i_{o} \cdot \rho/2 \cdot \pi \cdot d_{epi}) \ln (r/r_{1}).$$
Since  $v(r_{o}) = R = -(\rho/2 d_{epi}) \ln (r_{o}/r_{1})$ 
[3]

As a result, one obtains an increase of the spreading resistance for smaller dot diameters. For the epitaxial wafers of Figs. 2 and 3, we are not able to observe this change, first because the spreading resistance is too small, second, because the existence of the junction and oxide capacitance heavily interferes with the assumption of a simple radial current. For the SOS wafers shown here, however, the effect is clearly visible. For an oxide of 1300 Å, and an  $\sim$  10- $\mu$ m-thick epitaxial layer of 1 ohm-cm, one obtains R = 500, 1380, and  $\sim$  2450 ohms for dots of 0.01765, 0.00196, and 0.00049 cm<sup>2</sup>,

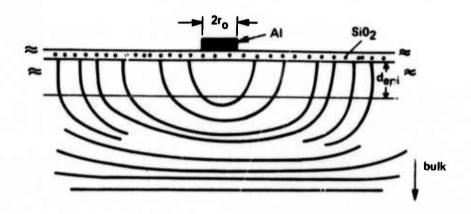

Fig. 5a. Equipotential lines for frequencies  $\ll 1$  MHz. The current flow in the epitaxial layer is practically radial.

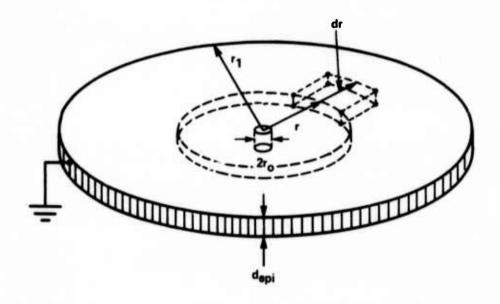

Fig. 5b. The epitaxial layer in a simplified disk-like geometry. For  $r < r_0$ , the potential is assumed to be constant (=  $v_0$ ).

respectively. Since, for these structures, contact with the backside is made by overlapping Al at the edge of the wafer, the spreading resistance is measured without distortion by the junction capacitance. Though we do not observe an R  $\alpha$  (-lnr $_0$ ) dependence but, rather, an R  $\alpha$  1/r $_0$  one, the model qualitatively describes the behavior of the spreading resistance.

# RANGE OF QUASI MOS CAPACITANCE TECHNIQUE

In the preceding sections, we have shown that the contribution of the junction impedance can be neglected, if appropriate values for the resistivities, oxide thickness, dot diameter, etc., are selected. In the following, we give approximate ranges for those parameters. Within these ranges, the junction impedance is small compared with the interface, oxide, and layer impedance.

For a 5-µm layer of  $\rho \sim 0.3$  ohm-cm resistivity and 1200 Å SiO $_2$ , a dot of d  $\leq$  0.5-mm diameter should be used. The substrate might have  $\rho \leq$  20 ohm-cm. For other oxide thicknesses d $_{\rm ox}$ , d can be chosen to be d =  $\frac{0.5}{1200}$  d $_{\rm ox}$ . For higher layer resistivities, the layer thickness should be increased according to the resistivity ratio. For epitaxial  $\rho$  values  $\geq$  15 ohm-cm, care must be taken that the condition  $C_{\rm ox}$  <<  $C_{\rm J}$  is still valid, e.g., by increasing the wafer area. For the insulator-silicon structure, with an oxide thickness of 1300 Å and a layer of

 $\sim 10~\mu m$  and  $N_D,~N_A \sim 1-2 \times 10^{16}~cm^{-3},$  we consider a dot of 0.25-mm dismeter as appropriate. The same changes in dot diameter and epitaxial layer thickness should be done for a variation in oxide thickness and layer resistivity. The diameter of the wafer should be at least 1-1/4 inches. Since these values refer to the oxide capacitance ( $\tau = RC_{\rm ox}$ ) and the lifetime measurements are carried out with the inversion and deep depletion capacitance (8), the accuracy increases by  $\left(C_{\rm ox}/C_{\rm f}\right)^2$ . (Cf. Eq. [1].)

## COMPARISON WITH OTHER TECHNIQUES

Finally, this technique should be compared with some alternatives, namely, the MOS emitter device and the buried-layer SOS structure, described, for example, in Refs. (9) and (10). Though some restricting conditions are implied in our technique, such as dot diameter, epitaxial layer thickness, etc., its advantages are greater versatility and measurement without distortion of a conduction layer. For example, the technique of Jones and Barber (9) is restricted to lifetimes, whereas a buried conduction layer (10) might cause outdiffusion and thus a reduction of lifetimes even in the epitaxial bulk.

Measurements using a guard ring as a counterelectrode were made. The substrate was at the same potential as the guard ring. The equivalent network consists of the oxide and space charge capacitance,  $C_{\rm ox}$  and  $C_{\rm sc}$ , respectively, of the dot

in series with the oxide capacitance  $C_{oxR}$ , the space charge capacitance  $C_{scR}$  of the ring, and the spreading resistance of the layer. The network is shunted by the coupling capacitance  $C_{c}$  between the dot and the ring. (We neglect here the shunt to the substrate, because this has been discussed above.) The condition  $C_{ox} \ll \frac{C_{oxR} \cdot C_{scR}}{C_{oxR} + C_{scR}}$  can be fulfilled by the appropriate choice of the ring area. The condition  $C_c << \frac{C_{ox} \cdot C_{sc}}{C_{ox} + C_{sc}}$  is always valid since oxide thicknesses of 500...5000 A are used. For a dot diameter of 60 mils, an oxide of 1000 Å, and a spacing of 150 µm, one obtains  $C_c = 10^{-4}$  pf. Thus dispersion-free C-V curves are feasible. This was confirmed by the experiment. However, a disadvantage is encountered: with the present state of the art, photoresist deteriorates the oxide and silicon properties, especially the lifetimes and the oxide stability. We observed reductions in lifetimes from 500 µsec to 0.1 µsec and flatband shifts. (The lifetime data of the paper were obtained by the technique given in Ref. 8.)

### RESULTS AND DISCUSSION

The results of the measurements can be summarized as follows: Flatband voltages and surface-state densities are found in the usual ranges of  $\sim$  -1V and  $\leq$  1.4x10<sup>10</sup> eV<sup>-1</sup> cm<sup>-2</sup>, respectively.

Since the peak of the G-V curves is found at depletion surface potentials for frequencies in the kHz range, the capture cross ection can be expected to be  $10^{-13}$  to  $10^{-15}$  cm<sup>2</sup>. No deviation compared with "normal" MOS structures can be seen. Lifetimes are measured to be 1 µsec in the epitaxial wafers,  $10^{-3}$  µsec in the n-SOS wafers, and 0.1 µsec in the p-SOS wafers.

The SOS low-frequency curves for wafers of layer thicknesses between 1 and 10 µm do not show any trace of a donor or an acceptor level (Fig. 6). This is in contradiction to earlier reports (11, 12), where an acceptor and a donor level at  $E_C - E_A = 0.25$  eV and  $E_D - E_V = 0.30$  eV were published. This might be attributed to different measurement techniques. The densities of the levels are reported to be  $10^{17}$  to  $10^{18}$  cm<sup>-3</sup>. A good resolution for surface states (or bulk impurities seen as surface states) for the slow ramp technique is  $10^{11}$  cm<sup>-2</sup>. If this value is divided by an effective distribution width of 10 to 100 %, one obtains bulk concentrations of 10 to 10<sup>18</sup> cm<sup>-3</sup>. The slow ramp technique, however, measures states localized at the surface, whereas the techniques used in Refs. (11) and (12) cover the rotal depth of the film. Thus, it might be concluded that the reported levels are located near the Si-Al<sub>2</sub>O<sub>3</sub> interface.

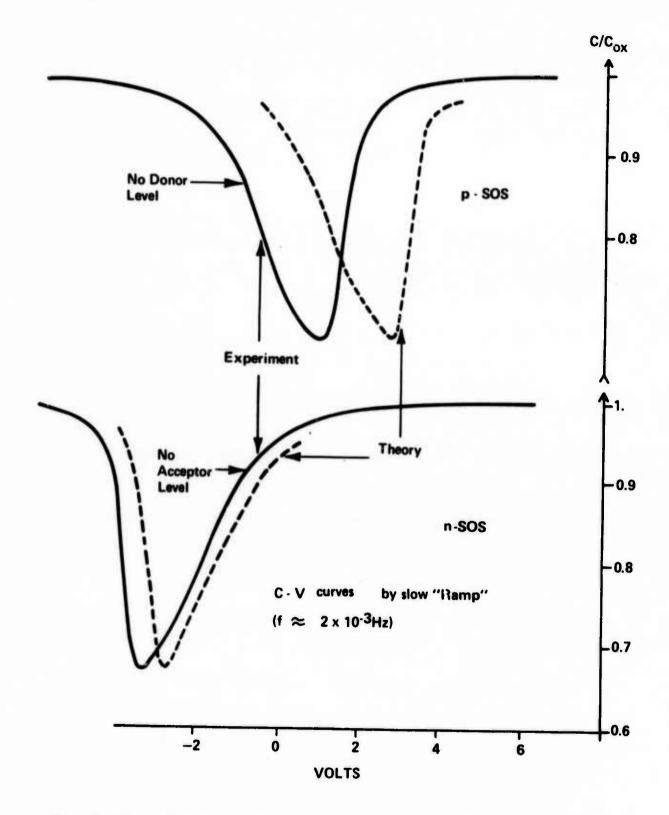

Fig. 6. Enlarged portion of the low frequency C-V curve of a p- and an n- SOS wafer. No indication of a deep lying level is visible. For comparison, the ideal low frequency curves are shown too.

Another possible explanation is the fact that one deals with extremely deep levels. Their time constant is controlled by the surface potential  $\mathbf{u}_{\mathbf{g}}$ :

$$\tau_p = (\sigma \cdot v_{th} \cdot N_A)^{-1} \exp(-u_s)$$

Since the levels are defined to be either acceptor or donor levels, they exchange carriers only with the valence or conductance band, respectively. With the given data and an assumption of a capture cross section  $\sigma = 10^{-15}$  cm<sup>2</sup> and a thermal velocity  $v_{th} = 10^7$  cm/sec, one obtains for the hole dispersion time constant in the n-type wafer  $\tau_p = 2 \times 10^2$  sec. This value is comparable to our measurement frequency of  $2 \times 10^{-3}$  Hz. Capture cross sections of  $10^{-15}$  cm<sup>2</sup> have been measured (13); in this case, however, higher values are more likely, and the first explanation should be preferred.

### SUMMARY AND CONCLUSIONS

The measurement of the admittance of an MOS structure over a p-n junction or on SOS devices is discussed. It is shown that by appropriate choice of the wafer data, the contribution of the junction to the total admittance can be neglected and lifetime measurement can be carried out.

No deep levels can be seen for the SOS system.
